AB Compositions and methods for the therapy and diagnosis of cancer, particularly colon cancer, are disclosed. Illustrative compositions comprise one or more colon tumor polypeptides, immunogenic portions thereof, polynucleotides that encode such polypeptides, antigen presenting cell that expresses such polypeptides, and T cells that are specific for cells expressing such polypeptides. The disclosed compositions are useful, for example, in the diagnosis, prevention and/or treatment of diseases, particularly colon cancer.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB This invention relates generally to the field of protein modification,

e.g., post-translational modification. In particular, the invention provides a method for detecting protein modification profile in a sample, which method comprises: a) contacting a sample containing or suspected of containing a target protein with a capture molecule, or a plurality of capture molecules, immobilized on a solid support, said capture molecule is capable of specifically binding to said target protein, whereby said target protein is immobilized on said solid support; and b) assessing modification status and/or identity of said immobilized target protein. Kits and arrays useful for detecting protein modification are also provided. Arrays, kits and methods useful for detecting enzymatic activities, especially protein modification enzymatic activities, are further provided.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB Provided herein are addressable collections of anti-tag capture agents, such as antibodies, that are used as tools for sorting proteins containing polypeptide tags for which the capture agents are specific. Also provided are methods of nested sorting using the collections. The methods include the steps of creating tagged collections of molecules by introducing a set of nucleic acid molecules that encode unique preselected polypeptides to create a library of tagged molecules; either before or after introducing the tags, dividing the library into N divisions; translating each division and reacting each with one of N capture agent collections, identifying the capture agents bound to the polypeptide tags linked to molecules of interest, and thereby identifying the one of the divided collections that contains the molecules of interest. The method can further include adding a new set of tags and repeating the sorting process with the same or a different collection capture agents and thereby identifying a protein or molecule of interest.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

NUMBER OF DRAWINGS:	9 Drawing Page(s)	
LINE COUNT:	1571	

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB A tethered reagent and assay is disclosed consisting of protein receptors tethered to ligands. The protein receptors can be antibodies, enzymes, hormone receptors, integral membrane proteins, and other proteins. Ligands can be antigens, enzymatic inhibitors, hormone agonists, drugs, and other protein binding ligands. The protein receptors and ligands will each be labeled with moieties capable of detecting changes in the average distance between the protein receptors and the ligand, using detection methods in which there is a sharp fall-off in signal as a function of distance. As a result, a change in the average distance between the two label moieties, such as that caused by protein-ligand binding and dissociation, produces a change in a detectable signal produced by the reagent. Tethering means may consist of flexible polymers, typically composed of a material that is chemically distinct from either the receptor or the ligand, so that the receptors and ligands may freely associate and dissociate via their specific binding sites, but not totally diffuse away from each other. When bound to solid phase surfaces, such reagents are particularly well suited for proteomic microarrays and flow cells. Such reagents may have utility for immunoassays, enzyme assays, ligand binding assays, sepsis assays, drug screening assays, and drug ADMET assays.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB Disclosed are compositions and methods for sensitive detection of one or multiple analytes. In general, the methods involve the use of special label components, referred to as reporter signals, that can be associated with, incorporated into, or otherwise linked to the analytes. In some embodiments, the reporter signals can be altered such that the altered forms of different reporter signals can be distinguished from each other. In some embodiments, sets of reporter signals can be used where two or more of the reporter signals in a set have one or more

common properties that allow the reporter signals having the common property to be distinguished and/or separated from other molecules lacking the common property. In other embodiments, sets of reporter signal/analyte conjugates can be used where two or more of the reporter signal/analyte conjugates in a set have one or more common properties that allow the reporter signal/analyte conjugates having the common property to be distinguished and/or separated from other molecules lacking the common property. Reporter signals can also be in conjunction with analytes (such as in mixtures of reporter signals and analytes), where no significant physical association between the reporter signals and analytes occurs; or alone, where no analyte is present.

AB Methods of using microarrays to simplify analysis and characterization of genes and their function are provided. Such methods can be used to identify and characterize antibodies having binding affinity for a specific target antigen. A method of determining gene expression at the protein level by contacting an array of characterized or uncharacterized antibodies on a solid surface with one or more proteins and identifying the antibodies to which said protein(s) binds also is provided. This method can be used to compare the protein expression in two different populations of cells, such as normal cells and cancer cells or resting cells and stimulated cells. In addition, a method of determining gene expression at the protein level by contacting a microarray of nucleic acid samples derived from a variety of different sources with one or more nucleic acid probes then identifying the sample or samples to which the probe binds is provided.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.
